SMALL BOWEL OBSTRUCTION DUE TO MECKEL’S DIVERTICULUM: A CASE REPORT
Malaya Krishna Nayak¹, Ashok Kumar Nayak², Rabinarayan Guru³, Sandeep Mishra⁴

HOW TO CITE THIS ARTICLE:

ABSTRACT: Meckel’s Diverticulum is the most common congenital anomaly of the intestine. Its common complications include hemorrhage, inflammation, and intestinal obstruction. Small bowel obstruction due to Meckel’s Diverticulum is a rare complication. Herein, we present a case of small bowel obstruction due to the mesodiverticular band of Meckel’s Diverticulum.

KEYWORDS: Meckel’s Diverticulum, Intestinal obstruction.

INTRODUCTION: Meckel’s Diverticulum is the most common congenital anomaly of the gastrointestinal system.¹,² It is caused by the failure of vitelline duct to obliterate.²,³,⁴ Most of them are detected incidentally during a surgical procedure or autopsy. Hemorrhage, intestinal obstruction and diverticulitis are the most common presenting features.³,⁴ This case report present small bowel obstruction due to mesodiverticular band of Meckel’s Diverticulum.

CASE REPORT: An 18 yr. old male presented to emergency OPD with complaints of an abdominal pain, vomiting & absolute constipation for 2 days. He was treated conservatively & referred from a local hospital. On admission, he was found having poor body build, dehydrated, ill looking. On examination, his abdomen was distended with diffuse tenderness & no palpable lump. Bowel sound was absent.

Digital rectal examination (DRE) revealed empty rectum. Plain X-ray abdomen in erect position showed gaseous distention with multiple air fluid level (fig.1). USG of abdomen showed dilated bowel loops with fluid. On investigation of blood, TLC was raised with Neutrophilia, and all other tests including serum electrolyte & renal function test were within normal limit. It was diagnosed to be a case of small gut obstruction and planed for exploratory laparotomy.

On exploratory laparotomy gross dilatation of the small gut and collapsed large gut were found. Dilation was up to the terminal ileum, about 2 feet away from the ileo-caecal valve, markedly compressed by a mesoventricular band leading to gangrene of that part (fig. 2). Obstruction was due to the trapping of small bowel by a mesodiverticular band (fig. 3). After separating the band ileal loops made free. Resection and end to end ileo-ileal anastomosis was done. Post-operative period was uneventful and the patient was discharged after the 7th day of hospitalization.

DISCUSSION: Meckel’s Diverticulum is the most common congenital anomaly of the gastrointestinal tract. Meckel's Diverticulum was first reported by Fabricius Hildanus in 1598 and then described in detail by Johann Friedrich Meckel, in 1809.²,³ It is the remnant of the persistent intestinal part of the vitello-intestinal or omphalo-enteric duct. It is true diverticulum found in the anti-mesenteric boarder comprising of all intestinal layers. It is found in 2% of total population, 2feet from the ileo-caecal junction, and 2 inch in length and has 2 types of common ectopic tissue (gastric and pancreatic).²,³,⁴
CASE REPORT

The frequent complications of Meckel’s Diverticulum are hemorrhage, intestinal obstruction and diverticulitis. Intestinal obstruction is the second common completion, which is due to trapping of bowel loops by mesodiverticular band, volvulus of the diverticulum, intussusception and Litre’s Hernia.\(^5\) In our case it was due to a mesoventricular band which could not be diagnosed by the conventional radiography or sonography.

Surgery is the main stay of treatment. The diverticulum is excised in a “V” form and small-intestine is sutured transversely. If the base of the diverticulum is wide or the intestine appears non-viable, resection and end to end ileo-ileal anastomosis may be required.\(^5\)
