UTERINE ARTERY DOPPLER IN THE PREDICTION OF PIH AND IUGR

P. Mathu Prabha¹, Divya Bharathi²

¹Senior Assistant, Professor and Registrar, Department of Obstetrics & Gynaecology, Tirunelveli Medical College Hospital.
²Senior Resident, Department of Obstetrics & Gynaecology, Tirunelveli Medical College Hospital.

ABSTRACT

AIM
Aim of this clinical study is to find out the sensitivity of uterine artery Doppler in prediction of hypertensive disorder in pregnancy and intrauterine growth restriction at 20-22 weeks of gestation, thereby to follow up the at risk patients and to improve perinatal outcome.

MATERIALS AND METHODS
The study was conducted at Tirunelveli Medical College Hospital from September 2013 to August 2014 in the Department of Obstetrics and Gynaecology and in the Department of Radiology.

About 200 antenatal mothers were selected and they were separated as (i) High risk (Group I), (ii) Low risk (Group II). High risk cases include 100 antenatal mothers with previous history of hypertension, FGR or IUD at 20-22 weeks of gestation. Low risk cases include 100 antenatal mothers (primi/multipara) at 20-22 weeks with no prior history of hypertension, FGR or IUD.

OBSERVATION
In Group I two cases (6.1%) had HTD, 15 cases (45.4%) had FGR in cases with persistence of bilateral notch in uterine artery. In Group I one case (20.0%) had HTD, 3 cases (60.0%) had FGR in cases with persistence of unilateral notch in uterine artery. In Group I four cases (6.7%) had HTD and 4 cases (6.7%) had FGR in case of absent notch in uterine artery. In Group II one case (8.3%) had HTD, 2 cases (16.7%) had FGR in presence of bilateral notch in uterine artery. In Group II, no cases reported to have HT in both unilateral and absent notches; one case (8.3%) had FGR in case of persistence of unilateral notch and no case had FGR in case of absent notch. Bilateral notch persistence was associated with severe form of HTD and FGR compared to unilateral notch in uterine artery. In this study in Group I in case of bilateral notch 61.1% had gestational HT, 8.2% had mild preeclampsia, 30.3% had severe preeclampsia. In case of unilateral notch 20.0% had gestational HT, 20.0% had mild preeclampsia, 20.0% had severe preeclampsia. In Group II in cases of persistence of bilateral notch 83.3% had gestational HT, 8.3% had mild preeclampsia, 8.3% had severe preeclampsia. In case of unilateral notch 16.7% had mild preeclampsia.

CONCLUSION
Though preeclampsia is not a preventable disease, early detection helps in increased foetal surveillance and timely interventions. From the study it is concluded that in Group I (High risk) in cases of bilateral notches there is increased risk of preeclampsia, FGR, and abnormal perinatal outcome compared to cases with unilateral notches and absent notch in uterine artery. In both Group I and Group II, bilateral diastolic notch was associated with poor prognosis. It is better to do Uterine Artery Doppler study along with targets scan at 20-22 weeks of gestation, thereby both anomalies of foetus and risk of preeclampsia; FGR can be predicted in the same visit. Cost of the test is the drawback in doing the test in government hospital. It is concluded from the study that in Group I and II, those cases with bilateral notch require more foetal surveillance and timely intervention compared to unilateral and absent notch. Cases with absent notches require only routine checkup and not frequent checkup.

Abbreviation:
HTD : Hypertensive Disease.
FGR : Foetal Growth Restriction.
IUD : Intrauterine Death.

KEYWORDS
HTD, FGR, Doppler Velocimetry.

INTRODUCTION
The primary aim of antenatal care is to achieve at the end of pregnancy a healthy mother and a healthy baby.

Recently, there have been many modern investigative and treatment modalities to provide good health care. Despite advances in antenatal care, hypertensive disorder in pregnancy contributes to increased maternal morbidity and mortality and thereby accounts for increased perinatal morbidity and mortality.

Major cause of maternal mortality according to 2001-2003 SRS survey are Haemorrhage (38%), sepsis (11%), hypertension (5%), obstructed labour (5%), abortion (8%) and other conditions (34%). As far as hypertension is considered, the main pathophysiology in preeclampsia and foetal growth restriction is impaired uteroplacental and foeto-placental circulation respectively.

Colour Doppler ultrasound of uterine artery at 20-22 weeks of gestation showing persistent diastolic notch helps in
predicting hypertensive disorder in pregnancy and intrauterine growth restriction.

Normally, the early diastolic notch persists till 22 weeks, after which there will be disappearance of diastolic notch. Persistence of diastolic notch beyond 22 weeks indicates defective placentation. The study is conducted to predict hypertensive disorder in pregnancy and intrauterine growth restriction by using uterine artery Doppler and thereby to follow-up the risk patients and to reduce both maternal and perinatal morbidity and mortality.

Foetal Growth Restriction (FGR)

Foetus with estimated weight below the 10th percentile for a given gestational age due to a pathologic process that inhibits intrinsic growth potential is called foetal growth restriction (ACOG-2000).

Incidence

10% in developing countries, 5-7% in developed countries.

Risk Factors for FGR

- Extremes of reproductive age (Younger than 16 yrs. and older than 35 yrs).
- Poor maternal weight gain.
- Poor pre-pregnancy weight.
- Severe malnutrition.
- Low socio-economic status.
- Maternal Medical Conditions.
  - Hypertension.
  - Renal disease.
  - Diabetes (With microvascular disease).
  - Cyanotic heart disease.
  - Antiphospholipid syndrome.
  - Collagen vascular disease.
  - Haemoglobinopathy.
  - Chromosomal anomalies.
  - Structural anomalies.
  - Primary placental disease.
  - Infections.
  - Exposure to teratogens.

AETIOPATHOGENESIS FACTORS IN FGR

Placental Causes

- Incomplete trophoblastic invasion of the spiral arteries in the placental bed.
- Accelerated atherosclerosis of spiral arteries.
- Increased number of syncytial knots, obliteration of arteries in tertiary stem villi, stromal fibrosis.
- Placental infarction and thrombosis due to factor V mutation and anti phospholipid syndrome.
- Endothelial dysfunctions due to decreased VEGF and PDGF and soluble endoglin decrease nitric oxide department vasodilation.

Maternal Causes

- Chronic hypertension
- Chronic renal disease
- Diabetes
- Preeclampsia
- Grade 3, 4 heart disease
- Smoking, alcohol, tobacco chewing
- SLE
- Fever, sickle cell anaemia, malnutrition

ANTENATAL DIAGNOSIS OF FGR

- Physical Examination
  - Discordance between gestational age and symphysio - fundal height > 4 cm. \(^1\)
- USG Parameters
  - Biparietal diameter, Head circumference, Abdominal circumference, Femur length, Estimated foetal weight.
  - Women with negative uterine Doppler screening are at low risk of FGR (Negative predictive value of 97% - 99%) \(^1\) and can be followed as normal pregnancies.
  - Uterine Artery Doppler Screening.
    - Presence of bilateral diastolic notch in uterine arteries is the predictor of FGR.

Diagnosis depends on

- Correct estimation of gestational age, preferably in the 1st trimester.
- Gestational age based on LMP using Naegle’s rule is uncertain in 20%-40% of cases.
- Gestational age is best established in 1st trimester using CRL measurement. Predictive error of EDD based on CRL is 7 days.

Integrated foetal testing:

- Baschat (2003) \(^2\) has suggested multiple testing to monitor FGR
  - Periodic foetal biometry.
  - AFL
  - Multi-vessel arterial and venous Doppler.
  - Biophysical Profile (BPP).
  - Foetal heart rate monitoring (CTG).
  - Foetal movement counting.

USG Parameters

- HC/AC Ratio.
  - It compares the most preserved organ (brain) with the most affected organ (liver).
  - HC/AC is normal in symmetric FGR.
  - HC/AC is increased in asymmetric FGR. >95 percentile for gestational age.
  - Normally, HC/AC ratio is >1 up to 36 weeks. After 36 weeks, the value of HC/AC ratio is <1.
  - Head circumference is measured at the level of thalami. Abdominal circumference is measured at the level of bifurcation of hepatic vein in the center of foetal liver.

1. Amniotic Fluid Volume (AFI)

AFI is important both in diagnosis and prognosis of FGR.

2. Growth Charts

Serial ultrasounds at intervals of two to four weeks for evaluation of foetal growth with the use of standardised growth curves demonstrate growth velocity.

3. Umbilical Artery Doppler

Umbilical artery Doppler helps to differentiate a normal small for gestational age foetus from the growth restricted foetus.

Doppler Study in Uteroplacental Insufficiency.

Doppler USG is used recently for assessing uteroplacental insufficiency, thereby preeclampsia and FGR is detected earlier. It was first demonstrated by Campbell in 1983. The
feasibility of its foetal application was demonstrated by Fitzgerald and Drum.

The uterine artery Doppler is measured at a point just distal to the crossover with the iliac artery before uterine artery divides into arcuate arteries.

Normal Uterine Artery Doppler Form
In non-pregnant women, there is a steep systolic flow and an early diastolic notch showing high vascular resistance. At 4 weeks after implantation, well-defined, low-resistant vessels are seen in future placenta. In second trimester uncoiling of uterine and spiral arteries occurs, so that low resistance occurs. In later trimester, there is a gradual removal of notch and increase in diastolic flow and decrease in resistance index. Resistance index was used as screening tool, but it has low sensitivity.

Bollar et al demonstrated that presence of notch in the artery homolateral to the placenta was associated with poor prognosis.

Michael S. Kraner et al mentioned environmental factors like stress, low socioeconomic status and overcrowded housing increase cortisol levels higher in maternal and foetal circulation and that leads to impaired placentation.

DIGITAT (Disproportionate Intrauterine Growth Intervention Trial At Term) study showed no difference in perinatal outcome, if after 36 weeks delivery was by induction of labour or by expectant management (Boers, 2010).^3^

Indices Used in Doppler
- Arterial system
- S/D ratio = systolic peak velocity/endpoint diastolic velocity.
- S-D/S = Resistance index.
- S-D/Mean frequency shift = Pulsatility Index

MATERIALS AND METHODS
The clinical study was conducted at Tirunelveli Medical College Hospital from September 2013 to August 2014 in the Department of Obstetrics and Gynaecology and in the Department of Radiology.

Selection of Cases
About 200 antenatal mothers were selected and they were separated as, (i) High risk (Group I), (ii) Low risk (Group II).

High risk cases include 100 antenatal mothers with previous history of hypertension, FGR, IUD at 20–22 weeks of gestation. Low risk cases include 100 antenatal mothers (primi/multipara) at 20–22 weeks with no prior history of hypertension, FGR or IUD.

Exclusion Criteria
Multiple gestations, Antenatal mother with cardiac diseases, DM, SLE, chronic hypertension and epilepsy.

METHOD OF STUDY
All antenatal mothers were registered in Antenatal OPD. A detailed history elicited and then examination done. After getting consent, Doppler study done at 20–22 weeks of gestation. The Doppler character studied for prediction of pre-eclampsia and FGR was bilateral diastolic notch.

Doppler Study Method
Antenatal mother is placed in a supine and slightly left lateral position to prevent supine hypotension. The frequency of Doppler used is 3.5-5 MHZ. Doppler measurement is done at a point just distal to the crossover with the iliac artery before uterine artery divides into arcuate arteries.

RESULTS AND ANALYSIS
Computer statistical analysis was used to analyse the statistics. Comparison of data was done using chi-square test. Multivariate analysis of data was done. Validity of the tests was evaluated by calculating sensitivity, specificity, positive and negative predictive values, likelihood ratio for positive and negative test with 95% confidence interval.

In Group I (High risk) 100 cases and in Group II (Low risk) 100 cases were selected and prospectively followed up; 3 cases in Group I and 2 cases in Group II were lost to follow up. The selected cases had uterine artery evaluation between 20-22 weeks gestation and followed up for development of hypertensive disorders, foetal growth restriction, gestational age at delivery, mode of delivery and perinatal outcome.

Table-I Notch Distribution

<table>
<thead>
<tr>
<th>Group-I</th>
<th>Group-II</th>
</tr>

Conclusion: Group I P=0.022, P value of 0.022 indicates significant relationship between notch and HTD-FGR. Group IIP = 0.007, P value of 0.007 indicate significant relationship between bilateral notch and HTD-FGR.
A study application was made feasible first by Fitzgerald and Drumm. It is a non-invasive technique, which uses high frequency sound waves for investigation of blood flow.

- In Group I, 2 cases (6.1%) had HTD; 15 cases (45.4%) had FGR in cases with persistence of bilateral notch.
- In Group II, 1 case (20.0%) had HTD, 3 cases (60.0%) had FGR in the case with persistence of unilateral notch.
- In Group I, 4 cases (6.7%) had HTD and 4 cases (6.7%) had FGR in case of absent notch.
- In Group II, 1 case (8.3%) had HTD; 2 cases (16.7%) had FGR in presence of bilateral notch.
- In Group II, no cases reported to have HT in both unilateral and absent notches.
- One case (8.3%) had FGR in case of persistence of unilateral notch and no case had FGR in case of absent notch.
- Bilateral notch persistence was associated with severe form of HTD and FGR compared to unilateral notch.
- Rofinas et al found persistence of diastolic notch in uterine artery with increased risk of HTD, FGR, caesarean delivery, preterm delivery and admission to NICU.
- According to NICE guideline, women with at least one high and 2 moderate risk factors of preeclampsia should be given 75 mg of Aspirin daily from 12 weeks of pregnancy till the delivery of the baby.
- SOGC guidelines (2008) suggest that women with mild-to-moderate HT and without co-morbid conditions should have antihypertensive to lower DBP to 80-105 mmHg. Hypertensive women with co-morbid conditions like DM, chronic HT and renal disease should have systolic BP 130-139 mmHg and DBP of 80-89 mmHg.
- Campbell et al first demonstrated relationship between HTD, FGR, foetal distress, increased caesarean delivery and low APGAR score with persistent bilateral diastolic notch.
- Deutinger et al found that early diastolic notch was associated with increased uteroplacental insufficiency.
- Pai found that in predicting HTD/FGR, persistent diastolic notch was a better parameter than resistant index.
- Zimmermann et al studied the utility of uterine artery Doppler between 21-24 weeks in prediction of preeclampsia and FGR. Doppler was less informative in cases of low risk. In case of bilateral notch, there is increased risk of preeclampsia and FGR. In case of bilateral notch, preeclampsia and FGR was noted in 58.3% compared to 8.3% in absent notch.
- Lesicher et al conducted the study after 26 weeks and found that early diastolic notch was associated with increased caesarean rate, preeclampsia, FGR, foetal distress and admission to NICU.
- Thaler et al found diastolic notch as a better outcome than S/D ratio and Resistance Index (RI).
- Bower et al also found correlation between diastolic notch and HTD, FGR, foetal distress.
- In this study, in Group I, in case of bilateral notch, 6.1% had gestational HT, 18.2% had mild preeclampsia, 30.3% had severe preeclampsia.
- In case of unilateral notch, 20.0% had gestational HT, 20.0% had mild preeclampsia, 20.0% had severe preeclampsia.
- In Group II in cases of persistence of bilateral notch 8.3% had gestational HT, 8.3% had mild preeclampsia, 8.3% had severe preeclampsia.
- In case of unilateral notch, 16.7% had mild preeclampsia.
- Aristidou et al and Christopher Lees demonstrated persistent diastolic notches with increased risk of HT, FGR and low APGAR scores.
- In this study, preterm delivery was more common in High risk (Group I) cases.
- In Group I, 30.3% had preterm delivery in case of bilateral notches and only 20.0% had preterm delivery in case of unilateral notches.
- The useful part of a test depends on negative predictive value. Negative predictive value of 100% in Group II (low risk) indicates that both HT/FGR will not be present.

**CONCLUSION**

- Though preeclampsia is not a preventable disease, early prediction helps in increased foetal surveillance and timely interventions.
- From the study it is concluded that in Group I and II, in case of bilateral notches there is increased risk of preeclampsia, FGR, preterm delivery and abnormal perinatal outcome compared to cases with unilateral notches and absent notches.
- In both Group I and Group II, bilateral diastolic notch was associated with poor prognosis.
- It is better to do Uterine Artery Doppler study along with target scan at 20-22 weeks of gestation, thereby both anomalies of foetus and risk of preeclampsia, FGR can be predicted in the same visit.
- Prediction value of Uterine Artery Doppler study is increased by doing the test along with serum beta HCG, PAPP-A and inhibin A.
- Cost of the test is the drawback in doing the test in government setup.
- From the study it is concluded that in Group I and II, those cases with bilateral notch require more foetal surveillance and timely intervention compared to unilateral and absent notch.
- Cases with absent notches require only routine checkups and not frequent checkups.
