HOW TO CITE THIS ARTICLE:

ABSTRACT: BACKGROUND: Type 2 diabetes mellitus (Type 2 DM) is a major metabolic disorder commonly associated with obesity. Obesity and Type 2 DM are closely associated with a state of low-grade inflammation which causes altered pulmonary function. There is faster decline in pulmonary function in obese Type 2 diabetic patients. OBJECTIVES: To study the correlation between glucose levels on pulmonary function tests in obese diabetic women. MATERIALS AND METHODS: 30 obese diabetic women aged between 30 & 65 yrs with duration of illness between 2 &10 yrs were selected for the study. Pulmonary function tests were performed using Medspiror. RESULTS AND CONCLUSION: Significant negative correlations were observed between the FVC, PEFR, mean FEF 25-75% and the raised blood glucose levels and that between the mean FEF 25-75% and the duration of Type 2 diabetes. This suggests that Type 2 diabetes is a risk factor for impairment of respiratory function in obese women and hence the metabolic pathways related to hyperglycemia make lungs to be potential targets.
KEYWORDS: Type 2 Diabetes, Pulmonary functions, Obese women.

INTRODUCTION: Diabetes mellitus comprises a group of metabolic disorder that share the phenotype of hyperglycemia. The metabolic dysregulation associated with it causes secondary pathophysiologic changes in multiple organ systems that impose a tremendous burden on an individual with diabetes and on the health care system.¹

Type 2 diabetes mellitus (Type 2 DM) is a major metabolic disorder also strongly associated with obesity. It appears to result from a collection of multiple genetic factors including polymorphisms, each contributing their own predisposing risks that are further modified by environmental factors. Obesity, particularly visceral, is very common in Type 2 DM. The relationship between them is of such interdependence that the term ‘diabesity’ has been coined. Adipocytes secrete a large number of biological products that modulate insulin secretion, insulin action and body weight, which may contribute to insulin resistance. Insulin resistance impairs glucose utilization by insulin sensitive tissues and increases hepatic glucose output; both of which contribute to hyperglycemia.²

Further, obesity and insulin resistance, the cardinal features of metabolic syndrome are closely associated with a state of low-grade inflammation.³ In adipose tissues, chronic over nutrition leads to macrophage infiltration resulting in local inflammation that aggravates insulin resistance. Moreover, systemic inflammation is also thought to play a role in the association between reduced pulmonary function and cardiovascular mortality.⁴ Thus, obesity and diabetes associated with inflammatory processes, cause altered pulmonary function. Data from the “atherosclerosis risk in communities” study showed a faster pulmonary function decline in Type 2 diabetics. This is undeniably significant because, airflow limitation is an independent predictor of death in Type 2 DM.¹
Although several studies have confirmed the effect of diabetes and obesity on pulmonary function, there are only a few studies designed to investigate whether poor glycemic control in obese Type 2 diabetic women is an independent determinant of reduced pulmonary function. Thus the present study was undertaken to study the correlation between glucose levels on respiratory function in obese diabetic women using the most important variables of pulmonary function tests.

MATERIALS AND METHODS: Thirty obese diabetic women aged between 30 & 65 yrs attending outpatient department in a tertiary care medical centre in Kuppam, Southern Andhra Pradesh, were selected for the study. The criteria for inclusion of the subjects were the following: obese diabetic individuals with duration of illness between 2 &10 yrs (BMI >25),5 non-smokers, subjects with no past history of chronic respiratory illness, subjects with no symptoms of respiratory illness at the time of examination, and subjects with no chronic cardiovascular disease.

A detailed health status assessment was done for all the subjects included in the study through history taking. Body mass index (BMI) was calculated after measuring height and weight. Clinical examination was done to rule out other systemic abnormalities. The ethical clearance was obtained. The subjects were briefed about the procedure and a written consent was taken. Then, every individual was subjected to pulmonary function tests.

Pulmonary function tests were performed using Medspiror, which is a PC based spirometer with a flow transducer. Tests were performed on all the subjects in sitting position. Reference values for spirometry were based on age, sex and height provided in the software.

The whole procedure was explained and demonstrated to the subjects before testing. Later the subjects were asked to perform the forced vital capacity manoeuvre. FVC was recorded after a maximal inspiration when the subject expired forcefully with maximum expiration in to the mouth piece. A minimum of 3 acceptable FVC manoeuvres were performed and the best manoeuvres were selected and accepted. Acceptability criteria were: full inhalation before the start of test, satisfactory start of exhalation (Maximal effort exerted with no hesitation), no cough during the 1st second of manoeuvre, no early termination of exhalation (A maximum exhalation time of 6 seconds was followed).

For FVC and FEV1 manoeuvres, only if the difference between the two largest values were not less than 200 ml and for PEFR, only if the difference between the two largest values were not less than 10%, the testing was continued for 8 trials and the values recorded. Calibration was done from time to time for accuracy. After scrutinizing the flow volume curve and the time volume curve, the parameters derived were FVC, FEV1, FEV1/FVC, PEFR and FEF-25-75%. These criteria are based on American thoracic society (ATS) and European thoracic society standards.

RESULTS: On assessing the relationship between duration of diabetes and pulmonary function as in Table, 1, significant negative correlation was observed with respect to mean FEF 25-75% suggesting an impairment of pulmonary function with prolonged duration of illness. On assessing the relationship between blood glucose levels and pulmonary functions as in Tables, 2 & 3, significant negative correlations were observed with respect to FVC, PEFR and mean FEF 25-75% suggesting an impairment of pulmonary function with increased blood glucose levels.
**DISCUSSION**: Obesity and Type 2 DM are two major features of metabolic syndrome, the prevalence of which has reached epidemic proportions. Obesity mechanically restricts lung volume in addition to causing widespread lipid deposition in non-adipose tissues including the lungs, which increases pro-oxidant and pro-inflammatory cellular stress as well as alterations in lung structure.\(^6\)

Dysregulation of adipokine secretion, free fatty acid toxicity, and site-specific differences in abdominal (visceral) and subcutaneous fat, support abdominal obesity as a causal factor mediating insulin resistance, increasing the risk of diabetes, in metabolic syndrome.\(^7\)
In the present study, it has been established that diabetes is a risk factor for impairment of respiratory function in obese women, notably, a negative correlation is obtained between blood glucose levels and the parameters of pulmonary function testing viz., FVC, FEF 25-75 and PEFR. This finding strongly suggests that the metabolic pathways related to hyperglycemia are the main factors accounting for impaired pulmonary function. The findings of the present study are in agreement with Walter. E, Robert et. al., who showed a decrease in FVC in patients with diabetes mellitus, Davis. M. E, Timothy, who studied pulmonary function and its association with Type 2 DM found an average decrease of 9.5% in FVC and Sreeja et.al., showed a reduction in PEF and mean FEF 25-75% in the case group.

The present study is also in agreement with findings of Tricia M. McKeever et.al., whose findings showed that post prandial glucose levels have an inverse association with pulmonary function suggesting that impaired glucose auto regulation is associated with impaired lung function.

On assessing the relationship between duration of diabetes with lung function, a significant negative correlation was found between the duration of diabetes and mean FEF 25-75% suggesting impairment of lung function with prolonged illness. The results of the present study is in agreement with Sultan A. Meo et.al., who studied the effect of duration of diabetes on ventilator function in ethnic Saudi group whose findings showed decreased FEF25-75% with the increased duration of disease.

The present study is also in agreement with the studies of Shravya K.G et.al., and Kanyakumari et.al., whose results showed a significant negative correlation between duration of diabetes and lung function.

The findings of the present study is also supported by Ramirez LC whose results showed that long-term near-normoglycemia may be beneficial in preventing the deterioration of pulmonary function associated with diabetes mellitus.

**CONCLUSION:** The results of the present study showed a decline in pulmonary function in obese Type 2 diabetic women with poor glycemic control. As measures of airflow limitation predict all-cause mortality in Type 2 diabetes, intensive glycemic management may reduce the risk of death through improved ventilatory function independent of other beneficial effects. Therefore, the impact of Type 2 diabetes on pulmonary function should be considered by those providing care for obese women.
