ABSTRACT

BACKGROUND

Chronic pulmonary diseases are a global health problem and the number of patients being treated in primary care settings is increasing. The prevalence of a life-time diagnosis of asthma has increased in all age groups. There has been a dramatic shift in the conceptualization and treatment of asthma and COPD in the last 50 years. Psychiatric disorders, especially anxiety disorders, are very common in patients with asthma and COPD. Anxiety is also common in COPD and is related to some of the same factors described for asthma including the psychological response to the experience of breathlessness as well as side effects of beta-agonists. Since there is paucity of relevant data from Kashmir, this study was designed to find the co morbidity in patients of COPD and Asthma in a tertiary care teaching hospital in Srinagar, Kashmir.

METHODS

Sixty successive patients presenting with history of thirty each of asthma and COPD who fulfilled inclusion and exclusion criteria were taken up for the study and administered the Hamilton depression rating scale (HAM-D) and Hamilton Anxiety rating scale (HAM-A) for evaluation of depressive disorder and anxiety disorder. Each patient was informed about the purpose of interview; his/her consent was obtained and strict confidentiality was ensured. General description, demographic data and psychiatric history were recorded using semi structured Proforma and HAM-A and HAM-D.

RESULTS

Out of sixty cases of COPD and Bronchial Asthma, 50% of the patients were in the age group of 66-80 followed by 35% in age group of 81-85 years. This could suggest that COPD and Bronchial Asthma is a problem of old age. There were predominantly more males (65%) than females (35%) in our study. Representations of gender, religion, family type and marital status have been found to be in accordance with socio-demographic profile of our country. Out of sixty cases of COPD and Bronchial Asthma, 35% of the patients were educated up to the primary level and 50% had poor social support. This reflects that low literacy rate along with presence of social support are factors of importance in COPD and Bronchial Asthma.

DISCUSSION

Depression was found in 35% of patients while anxiety disorder was found in majority of patients of 65%.

KEYWORDS

COPD, Asthma, Depression, Anxiety.

INTRODUCTION

Chronic pulmonary diseases are a global health problem and the number of patients being treated in primary care settings is increasing. The prevalence of a life-time diagnosis of asthma has increased in all age groups. Links between psychological factors and allergic disorders have been observed in clinical practice for centuries. There has been a dramatic shift in the conceptualization and treatment of asthma in the last 50 years or so. Acute exacerbations are a characteristic clinical expression of asthma and chronic obstructive pulmonary disease (COPD) and account for a significant amount of health care costs.

After hypertension, asthma is the most common chronic disease in the United States, affecting 5% to 7% of the population. Psychiatric disorders, especially anxiety disorders, are very common in patients with asthma. In youth with depression, asthma severity is increased relative to those with asthma alone. In adults with asthma, mental health problems are also associated with poor asthma control. Pulmonary function tends to be lower in people with asthma and depression or anxiety.

Adults, children and adolescents with asthma have a high prevalence of anxiety disorders. In adult populations with asthma, the estimated rate of panic disorder ranges from 6.5% to 24%. Individuals with asthma appear to have about a twofold higher risk of having one or more anxiety or depressive disorders. In a large population-based sample of adults, asthma was associated with a significantly increased likelihood of anxiety disorders (especially panic, generalized anxiety disorder, and phobias) and affective disorders. Depressive symptoms are also very common in asthma. Severe asthma can be very demoralizing and lead to learned helplessness.
In adults, particularly older adults, asthma is associated with higher rates of depression than other chronic illnesses, even after adjusting for psychosocial factors, physical comorbidity and the use of medications linked to depression. Anxiety and depressive symptoms are common in patients with COPD, even when their disease is mild. Anxiety is also common in COPD and is related to some of the same factors described for asthma including the psychological response to the experience of breathlessness as well as side effects of b-agonists. Therefore, this study was designed to find out depression and anxiety disorder in patients of COPD and Bronchial Asthma in a tertiary care teaching hospital in Srinagar.

AIMS & OBJECTIVES

Aim
To study the Psychiatric morbidities in patients of Chronic Obstructive Pulmonary Disease and Bronchial Asthma attending OPD of tertiary care hospital.

Objectives
To find out and study the socio-demographic profile and psychiatric morbidities using Hamilton depression rating scale (HAM-D) and Hamilton Anxiety rating scale (HAM-A) scales in patients presenting with COPD and Bronchial Asthma.

MATERIALS AND METHODS

Materials
1. Study Proforma: It consisted of a semi structured proforma to record the socio-demographic and respiratory status of the patient.
2. Hamilton Anxiety rating scale (HAM-A): HAM-A is one of the first rating scales developed to measure the severity of anxiety symptoms consists of 14 items. Each item has 4 options ranging from 0 (Not present) to 4 (Severe) with a total score ranging from 0-56, where <17 indicates mild severity, 18-24 mild to moderate severity and 25-30 moderate to severe. The patient responds to each and can complete the questionnaire in 15 minutes or less. The clinician can quickly score the questionnaire and identify those patients whose scores suggest the presence of anxiety.
3. Hamilton Depression rating scale (HAM-D): HAM-D is a designed to rate severity of depression in patients. It is to be administered by a health care profession. Although it contains 21 items, calculate the patients score on the first 17 answers. It has a total score of 88. 0-7 is considered to be normal, 8-13 is mild, 14-18 is moderate, 19-22 is severe and >23 is very severe depression.
4. Methodology
Study Site: Patients referred to the Department of Psychiatry of a tertiary care teaching hospital in Srinagar.

Inclusion Criteria
- Patients diagnosed with COPD and Bronchial Asthma referred to Psychiatry Department for evaluation.
- Patients between the ages of 30 to 90 years.

Exclusion Criteria
- Patients who did not give consent.
- Patients suffering from severe neurological illnesses.
- Patients suffering from severe psychiatric disorders.

Method
This was a hospital based cross-sectional observational study which included all referred patients with diagnosis of COPD and Bronchial Asthma to Department of Psychiatry for evaluation.

Successive patients satisfying the inclusion and exclusion criteria were taken up for the study and administered the Hamilton Anxiety rating scale (HAM-A) and Hamilton Depression rating scale (HAM-D) for evaluation of depression and anxiety.

Each patient was informed about the purpose of interview; his/her consent was obtained and strict confidentiality was ensured. The interview was conducted as soon as possible after the patient had satisfactorily recovered medically and was able to co-operate for the interview. Those patients referred to Psychiatry OPD for evaluation were interviewed in the outpatient department itself and other patients were interviewed in their respective wards of initial admission. General description, demographic data and psychiatric history were recorded using the self-designed proforma.

Statistics
Data was expressed in actual number, percentage and mean ± standard deviation. The Chi –square test was used for categorical data with ‘p’ value less than 0.05 taken as statistically significant.

Flow Chart

Data of 60 completed case record forms of patients collected
Data analyzed bio statistically
Results tabulated and discussed
Fig. 1: Gender wise distribution of Patients of COPD and Bronchial Asthma

There were predominantly more males (65%) than females (35%). Male patients had more percentage of Bronchial Asthma and COPD as compared to females.

50% of the patients were illiterate, while as 35% educated up to the primary level, 10% studied up to higher secondary while as 5% were graduate.

Fig. 2: Age wise distribution of patients of COPD and Bronchial Asthma

5% of patients were in the age group of 35-50 years, 10% patients between 51-65 years, 50% in the 66-80 years age group and 35% patients in the 81-85 years age group.

70% of the study sample resided in rural area while as rest of 30% resides in urban area.

Fig. 3: Distribution of COPD and Bronchial Asthma Patients according to their Marital Status

75% of the COPD and Bronchial Asthma patients were married and 25% were unmarried.

Fig. 4: Distribution of COPD and Bronchial Asthma patients as per their level of education

50% of patients had grade 3 dyspnoea, 40% had grade 2 dyspnea and rest of 10% of patients had grade 1 dyspnea.

Fig. 5: Distribution of COPD and Bronchial Asthma patients as per their residence

75% of the COPD and Bronchial Asthma patients as per their education...
The prevalence of both anxiety and depression disorders in male and female COPD and Bronchial Asthma patients with a wide range of disease severity. A recent study by Kunik et al. investigated the prevalence of anxiety and depression in a large sample of patients with chronic breathing disorders, including COPD, but the authors enrolled only patients who reported a significant level of anxiety and depression in a telephone screening. The significant findings of our study are as follows: (1) The prevalence of anxiety is very high as compared to depression in patients of both COPD and Bronchial Asthma; (2) Male patients have higher levels of anxiety and depression; (3) More patients had grade one dyspnea followed by grade two and then grade one. Female patients appear to be more susceptible to psychological impairment.

There were predominantly more males (65%) than females (35%). Male patients had more percentage of Bronchial Asthma and COPD as compared to females. According to Fabiano Di Marco et al., females were having more percentage as compared to males. 75% of the COPD and Bronchial Asthma patients were married and 25% were unmarried. 70% of the study sample resided in rural area while as rest of 30% resides in urban area. Representations of gender, religion, family type and marital status have been found to be in accordance with socio-demographic profile of our country. Our study shows 50% of patients had grade 3 dyspnea, 40% had grade 2 dyspnea and rest of 10% of patients had grade 1 dyspnea. 60% of patients had (FEV1)% up to 66%, while as 40% of patients had (FEV1)% more than 66%. C. P. Engström, L. O. Persson, et al. found out that forty-six patients with expiratory volume in one second (FEV1) below 50% predicted showed particularly high levels of dysfunction. Van Ede et al. underlined the lack of studies having adequate sample sizes.

In our study 60% of patients had hypertension followed by coronary heart disease in 30% and 10% patients had diabetes mellitus. This is supported in the study done by Schellevis FG et al. with similar findings. A literature review on the prevalence of anxiety in COPD patients reported rates of anxiety ranging from 10% to 40%. In our study prevalence of anxiety ranges to 65% as compared to 35% with depression. 50% of the patients had poor social and financial status, 30% had average and rest of 20% of patients had good social and financial status. 75% of patients had clear chest X-ray while as 25% had some pathology. More patients had good social and financial status. 75% of patients had clear chest X-ray while as 25% had some pathology. Out of sixty cases of COPD and Bronchial Asthma, fifty percent of the patients were in the age group of 66-80 followed by 35% in age group of 81-85 years. This could suggest that COPD and Bronchial Asthma is a problem of old age. This is supported by the study done by Jennifer A Cleland, Amanda J Lee, et al which showed old age has an impact on COPD. Keeping in view the findings it becomes mandatory for treating physicians to keep in mind need for psychological evaluation of such patients.

In this study an attempt has been made to find out the prevalence of depression and anxiety in patients of COPD and Bronchial Asthma in a tertiary care hospital Srinagar. Our study investigated the prevalence of both anxiety and depression disorders in male and female COPD and Bronchial Asthma patients with a wide range of disease severity. 60% of patients had (FEV1)% up to 66%, while as 40% of patients had (FEV1)% more than 66%.

There were predominantly more males (65%) than females (35%). Male patients had more percentage of Bronchial Asthma and COPD as compared to females. According to Fabiano Di Marco et al., females were having more percentage as compared to males. 75% of the COPD and Bronchial Asthma patients were married and 25% were unmarried. 70% of the study sample resided in rural area while as rest of 30% resides in urban area. Representations of gender, religion, family type and marital status have been found to be in accordance with socio-demographic profile of our country. Our study shows 50% of patients had grade 3 dyspnea, 40% had grade 2 dyspnea and rest of 10% of patients had grade 1 dyspnea. 60% of patients had (FEV1)% up to 66%, while as 40% of patients had (FEV1)% more than 66%. C. P. Engström, L. O. Persson, et al. found out that forty-six patients with expiratory volume in one second (FEV1) below 50% predicted showed particularly high levels of dysfunction. Van Ede et al. underlined the lack of studies having adequate sample sizes.

In our study 60% of patients had hypertension followed by coronary heart disease in 30% and 10% patients had diabetes mellitus. This is supported in the study done by Schellevis FG et al. with similar findings. A literature review on the prevalence of anxiety in COPD patients reported rates of anxiety ranging from 10% to 40%. In our study prevalence of anxiety ranges to 65% as compared to 35% with depression. 50% of the patients had poor social and financial status, 30% had average and rest of 20% of patients had good social and financial status. 75% of patients had clear chest X-ray while as 25% had some pathology. Out of sixty cases of COPD and Bronchial Asthma, fifty percent of the patients were in the age group of 66-80 followed by 35% in age group of 81-85 years. This could suggest that COPD and Bronchial Asthma is a problem of old age. This is supported by the study done by Jennifer A Cleland, Amanda J Lee, et al which showed old age has an impact on COPD. Keeping in view the findings it becomes mandatory for treating physicians to keep in mind need for psychological evaluation of such patients.
CONCLUSION
In this study we found that COPD and Bronchial Asthma was more common in old age people in this hospital based study. More than half of the patients were married with most of them being illiterate. More than 70% patients belonged to rural background. 50% of patients had poor financial status. 50% of patients had dyspnea of grade 3 severity, with FEV1 severity of up to 66% in 60% of patients.

75% of patients had no finding in x-ray chest while as remaining 25% showed pathology. All 100% of patients had a medical co-morbidity with hypertension found in 60% of patients followed by coronary heart disease in 30% of patients and diabetes in 105 of patients. Depression was found in 35% of patients while 65% had anxiety disorder as comorbid diagnosis.
