INTRODUCTION

“Prison” means any jail or place used permanently or temporarily under the general or special orders of a State Government for the detention of prisoners and includes all lands and buildings appurtenant thereto, but does not include (a) Any place for the confinement of prisoners who are exclusively in the custody of the police; (b) Any place specially appointed by the State Government under section 541 of the Code of Criminal Procedure 1882 (10 of 1882); or (c) Any place which has been declared by the State Government by general or special order to be a subsidiary jail.¹ Prisoners are one of the most underserved and neglected part of the population. The normal life of prisoners is restricted, freedom of movement is curtailed and private space is limited. India is home to 1387 jails with 4,18,536 inmates against a capacity of 3,56,561 at an occupancy rate of 117.4%. MP with 11 Central Jails, 33 Dist Jails, 78 sub-jails and an open jail has 36,433 inmates against a capacity of 27,427 with an occupancy rate of 133.7%. This highlights the overcrowded condition in which prisoners have to live in.² The psychological burden, overcrowded unhygienic living conditions and neglected healthcare render the inmates to a higher risk of contracting an array of illnesses like sexually transmissible diseases, drug abuse, psychosis, community-acquired diseases and malnutrition. The present study was conducted on the prisoners admitted in surgical ward of Sanjay Gandhi Hospital during 2011-2015 with objective of estimating the prevalence of various surgical diseases they suffer from, highlighting the problem of anaemia, hypoalbuminemia and latent jaundice prevalent in this population and recommending necessary nutritional corrections.

BACKGROUND

Health care of prisoners is one of the most neglected issues. Estimating common healthcare problems plaguing prisoners will be helpful in assessing their health status and recommending the rectifying steps.

OBJECTIVES

To estimate the prevalence of surgical diseases and occult parameters of malnutrition among prisoners and recommend the correctional measures.

MATERIALS AND METHODS

A hospital-based retrospective study was conducted on 71 prisoners admitted in surgical ward of a tertiary care centre in the Vindhya region spanning a period of 5 years (2011-2015) and the information from their case sheets was tabulated and subjected to statistical analysis.

RESULTS

Gastrointestinal diseases (23.9%), Anorectal diseases (18.3%), Genitourinary diseases (16.9%), cellulitis and abscesses (12.7%) constituted more than two-thirds of all cases. Half the patients were anemic; 80% of the patients had hypoalbuminemia and one-third of the patients had raised Serum Bilirubin level, though they did not present with jaundice.

CONCLUSION

Surgical diseases related to infectious aetiology and poor personal hygiene are particularly common in prisoners and they suffer from a host of underlying malnutritional and systemic diseases in the form of organ dysfunction and nutritional supplementation and regular health check-up is recommended to overcome the problem.

KEYWORDS

Infectious, Anaemia, Hypoalbuminemia, Jaundice, Malnutrition, Organ Dysfunction.
MATERIALS AND METHODS
This is a hospital-based retrospective study in which the details of all 71 prisoners admitted in the surgical ward of Sanjay Gandhi Memorial Hospital, Rewa, (MP) between 2011 and 2015 were collected from their case sheets stored in the Central Registration Section of the Department of Surgery, S.S. Medical College, Rewa, without applying any exclusion criteria. Information about the age, gender, presenting complaints along with their duration, all investigations done, the final diagnosis and mode of treatment done was tabulated and subjected to statistical analysis and conclusions were drawn.

AIMS AND OBJECTIVES
1. To estimate the prevalence of various surgical diseases affecting the prisoners admitted in the surgical ward of S.S. Medical College, Rewa, (MP) between 2011 and 2015.
2. To highlight the problem of anaemia, hypoalbuminemia and latent jaundice in the prisoners.
3. To recommend correctional steps to overcome this problem.

Dent. Sci./eISSN- 2278-4802, pISSN- 2278-4748/ Vol. 5/ Issue 40/ May 19, 2016  

- 5.6% of the patients had Cancer.
- 2.8% of the patients were HIV positive.
- 2.8% of the patients had TB.

60 out of 71 patients under study were subjected to Random Blood Sugar testing; 8.3% pts. were known diabetic and on anti-diabetic medication, while another 13.3% of the pts. were found to have hyperglycaemia after admission. Added together more than one-fifth of the patients were not euglycemics.

60 pts. were subjected to renal function tests; 16.6% pts. had deranged renal function.

Haemoglobin was measured in 68 out of 71 patients. Half the patients were found to be anaemic (Hb <12 gm%), out of which 32.3% patients had mild anaemia (Hb 9.1–12 gm%), 11.8% patients had moderate anaemia (Hb 6.1–9 gm%) and 5.9% patients had severe anaemia (Hb 6 gm% or less).

Serum albumin was done in 25 out of 71 patients; 80% of the patients had hypoalbuminemia, while only 20% pts. had normal albumin level.

Serum bilirubin was done in 48 out of 71 patients. Though none of the pt. came with a complaint of icterus, one-third of them had raised serum bilirubin level out of whom 29.17% pts. had latent jaundice (Serum Bilirubin 1–2 mg%) and 4.16% patients had clinical jaundice (Serum Bilirubin >2 mg%).

DISCUSSION

In our study, the patients were male. This finding is consistent with the NCRB data according to which 95.8% of the prisoners are male.2 Sunil D. Kumar et al in their study conducted in a Central Jail in Gulbarga found that 95.7% of the prisoners were males.3 Asha A. Bellad et al in their study on prisoners conducted in the Central Jail of Hindalga, Belgaum, found that 92% inmates were males.4 This may be because our population is a male-dominated society; men have greater involvement in the matters outside the household. They move about in society more freely than women and therefore are more likely to commit crime.

In our study, 81.7% patients were in below 50 years of age. The corresponding figures of NCRB is similar and stands at 87.1%.2 Sunil D. Kumar et al in their study reported 76% of the prisoners under 50 years of age.3 R.K. Gupta et al in their study on inmates of Yerwada Jail, Pune, reported 81.5% prisoners under the age of 50 years.5 A younger person can be thought to have a greater vulnerability to take deviant ways as well as greater ability to perform a crime. At this age, there are generally problems like family feuds and unemployment which might lead to an increase in crime.

The duration of hospitalization depends on the severity of illness of the patient as well as availability of healthcare services in the treating hospital in the form of infrastructure, manpower and promptness of management. According to the severity of illness, prisoners were kept hospitalized for a duration ranging from 2 days to more than 5 months with an average duration of 15 days.

About half of the patients with acute presentation presented after 7 days of the onset of complaints, while 90% of those with chronic complaints presented after 1 month of onset of complaints, which highlights the lack of health awareness among the prisoners as well as the lack of access to quality primary healthcare services.

More than 70% of the prisoners under study suffered from infective or inflammatory diseases of gastrointestinal, anorectal, genitourinary or skin and soft tissue systems. Sunil D. Kumar et al in his study found 37% of the prisoners suffered from infectious diseases.2 R.K. Gupta et al in his study reported that more than 80% of the prisoners suffered from diseases pertaining to these systems and more than half the prisoners were harbouring infections in their skin as well as gut.5 Baillargeon J et al in their study on prisoners of Texas found that infectious disease constitute 29% of the total disease burden.6 Overcrowding, poor personal hygiene and lack of access to clean water can be counted as the possible reasons behind the high prevalence of infectious diseases among the prisoners.

In our study, 5.6% (n=4) of the prisoners had cancer. Paul Mathew et al in their extensive hospital-based study of 20 years on the inmates of Texas Department of Criminal Justice found that 1953 inmates had developed Cancer between January 1, 1980 and December 31, 1999. The study estimated that nearly 3000 inmates in the U.S. are diagnosed with cancer annually and the numbers of inmates diagnosed with cancer rose proportionately as the prison population increased rapidly in the latter part of the last century.7

In our study, 2.8% of the prisoners were HIV positive. R.K. Gupta et al reported a prevalence of 0.4%.3 Sunil D. Kumar et al reported a figure of 0.33%.3 Asha A. Bellad et al in their study reported a prevalence of 1.5% for HIV positivity among prisoners.5 Kate Dolan et al in their study on HIV in Indian prisons quote a figure of 1.7% and 9.5% as prevalence of HIV positivity for male and female prisoners in India respectively and attribute unprotected sex among prisoners as a common cause behind the phenomenon.8

In the present study, 2.8% (n=2) of the prisoners had TB. R.K. Gupta et al reported a prevalence of 7.5%.5 Asha A. Bellad et al reported a prevalence of 2%,4 while Baillargeon J. et al reported a prevalence as high as 20.1%.6 Overcrowding and sub-standard living conditions are the possible leading factors behind the unabated transmission of the tubercular bacilli among the prisoners.

In our study, more than 21.6% patients were found to have hyperglycaemia and were either already on anti-diabetic medication or were started on anti-diabetic therapy after admission. Sunil D. Kumar et al reported a 2.33% prevalence of Diabetes Mellitus.2 Asha A. Bellad et al reported a prevalence of 3.6% for Diabetes.4

In our study 1 in every 7 prisoners had an undiagnosed Diabetes, 1 in every 6 prisoners had an undiagnosed renal dysfunction, while one-third of all prisoners had undiagnosed liver compromise in the form of raised Serum Bilirubin and decreased Serum Albumin. This underscores the lack of routine health check-ups in prisoners and their need to pickup the cases early for effective management before the disease becomes uncontrollable.

In our study, 50% of the prisoners were anaemic. R.K. Gupta et al reported a prevalence of 20.7% for pallor and 17.6% for anaemia among prisoners and quote an average annual hospitalization rate of 5.7% for anaemia among state prisons.5 Sunil D. Kumar et al reported a prevalence of 84% for anaemia.3

In our study, 80% of the prisoners tested for Serum Albumin level showed a value lower than normal. Olobudun JO et al in their study found that prisoners had lesser BMI (48.1%
as compared to 28.6% for BMI less than 20 kg/m²), lesser mean Serum Protein (81.5 gm/L as compared to 88.7 gm/L) and Mean Serum Albumin levels when compared with the general population and attributed the predominantly carbohydrate diet as a causative factor behind the phenomenon.9

This signifies the lack of iron and protein supplements in the diet provided to the prisoners and underscores the need of overhauling the nutritional strategy for the prisoners and providing iron and protein rich diet for all prisoners and supplementing the same for those who are deficient in these nutrients.

Limitations of the Study
This is a hospital-based study with the prisoners admitted in surgical ward acting as the study population. A population-based study conducted on all prisoners of all jails of the region would have been more comprehensive. This is a retrospective study. A prospective study with direct interviewing and clinical examination of the patients would have been more fruitful. Inclusion of the dietary provisions and condition of hygiene after getting the relevant information from direct visit to the prisons would lead to pinpointing of the cause and making evidence-based recommendations.

CONCLUSION
"It is said that no one truly knows a nation until one has been inside its jails. A nation should not be judged by how it treats its highest citizens, but its lowest ones." 10

Nelson Mandela
Prisoners form a closed, overcrowded population overburdened with diseases. They are particularly prone to infectious diseases, substance abuse, psychiatric problems and malnutrition. In this study conducted on prisoners admitted in surgical ward, the problem of occult hypoalbuminemia, anaemia, diabetes and compromised liver and renal function have come up as an alarming problem and an eye-opener for the healthcare providers. Regular health check-up and improving the nutrition status as well as the living conditions will go a long way in improving the healthcare status of the prisoners. If the inmates are treated adequately in jails, they will return to the community health and will not burden the existing healthcare facilities of the country.

RECOMMENDATION
Though most of the patients came for other complaints, on routine investigations half the patients were found to be anaemic, 4 in every 5 had hypoalbuminemia, one-third had compromised hepatic function, one-fifths had diabetes or pre-diabetes and 1 in every 6 had deranged renal function. This underscores the lack of routine health check-up in prisoners and a need for regular health check-up supplemented with routine investigations, so that these features of malnutrition and end-organ failure can be picked up early and subjected to definitive therapy at a stage where it is amenable to treatment. Special care needs to be taken regarding diet of prisoners, especially pertaining to iron and protein contents. The service of a qualified nutritionist needs to be sought and protein and iron need to be provided to all prisoners and supplemented to them who are suffering from the deficiency of these nutrients. Infectious diseases and diseases related to poor hygiene have a lion’s share in the prevalence of surgical diseases among prisoners. These problems stem out from the menace of overcrowding. A holistic approach to the healthcare needs to be taken and prisoners must be provided with hygienic living condition along with access to safe water and sanitation facilities.

There must be regular health awareness programmes among the prisoners in the form of workshops, symposium, didactic lectures as well as printed literature, wherein they must be taught to identify the early symptoms of common diseases so that they can report to the healthcare staff at the earliest appearance of the symptoms. The educational material must include tools to enrich the knowledge of the prisoners regarding the principles of being healthy.
