**ABSTRACT**

**BACKGROUND**

Diabetic foot infections can be devastating, often eventuating in hospitalisation and occasionally a lower extremity amputation. Over the past three decades, studies have provided data with which evidence-based guidelines were developed. These have used a methodical approach to evaluate the available evidence on determining which diabetic foot wounds are infected, how to culture these wounds, what local care and surgical procedures are most appropriate and how to approach providing optimal antibiotic therapy.

**MATERIALS AND METHODS**

This prospective study included 71 and 53 consecutive patients with diabetes and non-diabetics respectively with various wound infections; exudates were inoculated on nutrient agar, blood agar, MacConkey agar and chocolate agar plates for the isolation of aerobic bacteria and antibiotic susceptibility testing was performed.

**RESULTS**

A total number of ulcer samples analysed were 255,318 from Diabetes Mellitus (DM) and Non-Diabetes Mellitus (NDM) respectively. The isolates of culture positive were 71 (27.84%) and 53 (16.67%). In diabetic group more resistance were penicillin (100%), azithromycin (87.32%), cefotaxime (88.73%), erythromycin (92.96%) and polymyxin B (78.87%). In non-diabetic group, more resistance were penicillin (98.11%), cefotaxime (75.47%) and erythromycin (88.68%).

**CONCLUSION**

Rate of antibiotic resistance was more in diabetic persons. They are prone for variety of infections when compared with non-diabetic mellitus. In both groups aztreonam, amikacin, gentamicin, tetracycline, vancomycin and imipenem were the most useful antibiotics.

**BACKGROUND**

Insulin is an enzyme secreting by pancreas gland. When insulin decreased in secretion or action, that disease is called as diabetes. In 21st century diabetic and cardiovascular disease are emerging infections to mankind. Approximately, 320 million persons will be diabetic in end of 2025. Diabetic persons are also associated with reduced immunity system like decreased response of T-cell and its activity, etc. The epidemiology of diabetic chronic wound infections due to countless studies surveying the associated microorganisms. Although, the specific percentages differ from study to study, the most predominant aerobes are Staphylococcus aureus, coagulase-negative Staphylococci, Streptococcus species, Enterococcus species, Corynebacterium species, Enterobacteriaceae and Pseudomonas aeruginosa. Multidrug Resistant Organisms (MDRO) are defined as microorganisms that are resistant to two or more classes of antimicrobial agents. For diabetics, the risk factors associated with acquiring an MDRO infection have been identified and include previous antibiotic therapy and its duration, frequency of hospitalisation, duration of hospital stays, osteomyelitis and proliferative retinopathy. These risk factors would suggest that MDRO infection rates would be higher in the diabetic population versus the non-diabetic population; there have been no reports directly comparing the rates of MDRO infections in diabetic versus non-diabetic wounds. The goal of this study was to determine if infections with MDRO occurred more in the diabetic population, and if so which bacterial species were most prevalent. Approximately, one-fourth of people with diabetes will develop an ulcer during their lifetime and as many as half of these ulcers will become infected. Diabetic foot ulcers are colonized by pathogenic bacteria that may predispose a susceptible patient to a lower extremity infection, defined as the invasion and multiplication of...
microorganisms in body tissues associated with tissue destruction or host inflammatory responses.[11]

In people with diabetes wounds/ulcers, several factors such as inappropriate antibiotic treatment, the chronic nature of the wound and frequent hospital admission can influence the presence of multidrug-resistant microorganisms in the ulcer. Recurrent pathogenic MDR strains can cause amputation, increased hospital stay, morbidity and mortality in diabetic persons. Therefore, the aim of the present study was to evaluate the bacteriological profile and drug resistance association of wound infections with and of diabetic at Rajiv Gandhi Institute of Medical Sciences (RIMS), Srikakulam, Andhra Pradesh in order to determine the relative frequencies of pathogens from wound infections and to study the in vitro antibiotic resistance.

MATERIALS AND METHODS
Study Design
This prospective study included 71 and 53 consecutive patients with diabetes and non-diabetic respectively with various wound infection, who were Outpatient (OP) and Inpatient (IP) attended departments like General Medicine, Dental, Surgery, Orthopaedics, ENT of the Rajiv Gandhi Institute of Medical Sciences, Srikakulam between January 2016 and October 2016. The Hospital is a 500-bedded tertiary care hospital utilised by people from most backward area of Srikakulam district and its surrounding areas. Demographic and lesion data including all types of wound infection of diabetic and non-diabetic patients, features of the lesion and location of the lesion were recorded for each patient.

Characterisation of Bacterial Isolates
Culture specimens were collected using sterile cotton swabs. To eliminate the possibility of isolating colonising bacteria, all type of wounds were included in the study. After cleaning the wound site with sterile normal saline, swab samples were collected aseptically and transported immediately in Stuart medium to laboratory. The specimens were inoculated on blood agar, chocolate agar, MacConkey agar and nutrient agar plates, incubated aerobically at 37°C for 24 hours. The isolates were further confirmed by gram-staining, colony morphology, hanging drop, an oxidase test, catalase test, slide and tube coagulase test and various biochemical tests.[12] In this study, anaerobic bacteria excluded.

Antibiotic Sensitivity Testing
Antibiotic sensitivity testing was performed by standard Kirby Bauer disk diffusion method followed to the Clinical and Laboratory Standards Institute (CLSI) guidelines.[13] The antibiotics used for Gram-positive bacteria were Cefoxitin, azithromycin, amoxicillin/davulanic acid, imipenem, cephalaxin, vancomycin, trimethoprim-sulfamethoxazole, oxacillin, penicillin and erythromycin. For Gram-negative bacteria were gentamicin, amoxicillin, norfloxacin, tetracycline, ampicillin, aztreonam, cefotaxime, imipenem, polymyxin B, amoxicillin/clavulanic acid and ceftoxin. Interpreted according to the criteria of the CLSI.[14] Multidrug-Resistant Organisms (MDRO) were defined as bacteria that were resistant to more than one or all classes of antibiotics.

Ethical Considerations
The study was conducted after receiving approval of Ethics Committee in RIMS, Srikakulam (Rc No. Spl/EC/08/2016) and after obtaining informed consent subjects only.

Statistical Analyses
Used SPSS 16.0 version software were applied by bar diagram and chi-square (χ2) test a probability of 0.05 is taken as statistically significant.

Table 4. Isolation of Pathogens by Species

Isolation of Pathogens by Species
Isolation of gram positive pathogen like S. aureus 23 (32.39%), 21 (39.62%) were more and gram negative classification pseudomonas 17 (23.94%), 9 (16.98%) in diabetes and non-diabetes mellitus groups respectively as shown in Table 4. There is no significant difference (P > 0.05) between diabetes mellitus versus non-diabetes mellitus groups and pathogenic species.

Figure 1. Antibiotic Sensitivity of Diabetes and Non-Diabetes Mellitus Pathogens
Antibiotic Sensitivity of Diabetes and Non-Diabetes Mellitus Pathogens

In diabetic group more resistance were penicillin (100%), azithromycin (87.32%), cefotaxime (88.73%), erythromycin (92.96%) and polymyxin B (78.87%). In non-diabetic group more resistance were cefotaxime (75.47%), erythromycin (88.68%) and penicillin (98.11%) as shown in Figure 1.

DISCUSSION

The prognosis of diabetic foot infections remains poor and the outcomes have been reported to be worse with MDR pathogens than with non-MDR pathogens in patients with diabetic wound infections.[10] Our study showed more MDR strains appeared in diabetic persons who were hospitalised, chronically wounded,[12,13] and few patients underwent some type of amputation. However, wound infections are associated with mono or polymicrobial infections. Moderate-to-severe infections often necessitate empirical regimens with activity against commonly isolated gram-negative bacilli, MRSA and perhaps Enterococcus spp.[16]

The rate of wound infections vary widely between institutions, areas and site of infection. The current study showed more Multidrug Resistance (MDR) strains found in diabetic group. Mild infections are often managed with local wound care strategies and/or prophylactic measures. It is important to note that the decisions relating to the antibiotic treatment of wounds are influenced by clinical evidence, the availability of appropriate antibiotic interventions, patient’s requirement and practitioner’s expertise.[13]

This study is limited by the aerobic bacteria evaluation, but anaerobic bacteria could not be investigated. Wound infections often associated with aerobic pathogens majorly[17,18,19,20] and evaluated gram-positive bacteria were predominant in diabetic wound infections, in case of non-diabetic wound infections gram negative bacteria were more similar findings also mentioned by Abdulrazak et al, Wang et al and Urvish et al.[21,22,23]

The study revealed diabetic wound infections are associated with MDR strains of gram positive and gram negative pathogens and were resistant to routine antibiotics. Pseudomonas, Staphylococcus and Streptococcus infections were predominant in diabetic persons.[24,25] Possible reasons for these differences by hypoxia, hyperglycaemia, etc., longer duration of infection, more frequent hospital exposures and extended periods of antibiotic use, all of which can influence shifts in the wound microbiota.

Moreover, Proteus spp. was resistant to all betalactamics except imipenem, cefoxitin and gentamicin. Proteus spp. are known to produce a unique β-lactamase that has high activity against antibiotics, primarily cefotaxime[26] a third-generation cephalosporin. Furthermore, Escherichia coli were resistant to the majority of antibiotics tested, except gentamicin and imipenem.[27,28]

CONCLUSION

The present study report has some limitations, because cultures for aerobic bacteria could be performed and diabetic wound infections were predominantly due to gram-negative bacteria. Antibiotic resistance rate more in diabetic persons prone for variety of infections when compared with non-diabetic mellitus. Amikacin, aztreonam, gentamicin, vancomycin, tetracycline and imipenem were the most effective antibiotics against almost all bacteria in both groups.
