HOW TO CITE THIS ARTICLE:

ABSTRACT: Benign (Jessners) lymphocytic infiltration of the skin is a chronic, benign T-cell infiltrative disorder, usually manifesting as erythematous papules or plaques on the face, neck and back. We report the case of a 30-year-old female, who presented with erythematous papules and plaques on face, upper back, front of chest, of 4 months duration and erythematous plaque on both dorsa of hand and forearms of 1 month duration. Skin biopsy confirmed the diagnosis of Jessner's lymphocytic infiltration of the skin. The evolution was favorable with hydroxy chloroquine.

KEYWORDS: Benign (Jessners) lymphocytic infiltration of skin, hydroxy chloroquine.

INTRODUCTION: Jessner's (benign) lymphocytic infiltration of the skin (JLIS) is a skin condition of unknown aetiology characterized by erythematous papules and plaques located on the head, neck and upper back. The eruption resolves spontaneously after months or a few years but can recur for several years. A variety of empirical treatments has been tried with limited success. Here we report a case of Jessner's lymphocytic infiltration of skin successfully treated with hydroxychloroquine.

CASE REPORT: A 30 year old female presented with history of erythematous papules and plaques on the face, upper back, front of chest, of 4 months duration and erythematous plaque on both dorsa of hand and forearm of 4 month duration. The present complaint started as small erythematous lesion 0.5 cm size on the forehead, nose, upper back followed by involvement of dorsa forearm and hands. There is history of increased erythema and burning sensation on exposure to sunlight. There is no history of oral ulcers, arthralgia. No history of aggravation with intake of spicy foods & alcohol. No history of loss of weight & loss of appetite. No history of similar complaints in the past. No history of diabetes mellitus, hypertension, jaundice & psoriasis.

She is moderately built & moderately nourished, no cyanosis, no clubbing, no jaundice, no generalized lymphadenopathy.

Cutaneous examination (Fig. 1- a, b, c) showed well defined erythematous infiltrated plaque, few erythematous papules and plaques over the forehead, nose upper back, dorsa of forearm and hands. Oral cavity, nails, palms & soles were normal.
Differential diagnosis of tumid DLE, Jessners lymphocytic infiltration of the skin, polymorphic light eruption, sarcoidosis and rosacea were considered.

Haematological investigations, renal, liver & thyroid function tests, borrelia serology, screening for ANA was done. All are with in normal limits. Skin biopsy was taken.

Histopathological findings (Fig. 2 10x&40x), Epidermis shows focal thinning. Basal layer intact. There is oedema in papillary and upper dermis and congested vessels. There are foci of perivascular dense lymphoid aggregates and occasional plasma cells. Vascular channels appear to be proliferated with prominent endothelial cells. Collagen in the upper and mid dermis appear swollen and edematous.
CASE REPORT

Direct immunofluorescence negative.
Mantoux – 7 mm induration.
Chest x ray was normal.

Basing on history, clinical features and histopathological findings diagnosis of Jessners (benign) lymphocytic infiltration of the skin was made.

After confirming the diagnosis, we put the patient on Tab. Hydroxy chloroquine 200 mg BID tapered over a period of 6 weeks along with topical sunscreen.

Skin lesions subsided after 6 weeks treatment (Fig. 3). Treatment was stopped and the patient was followed up for 1 year. There was no recurrence of the lesions till now.

DISCUSSION: JLIS, described by Jessner & Kanof in 1953,(1) is known as a benign chronic T-cell infiltrative disorder with lesions persisting for several months or years. Spontaneous remission may be seen, but JLIS has a tendency to relapse.

The incidence of JLIS is unknown, but it is considered uncommon. It mostly affects middle-aged adults, with equal incidence in men and women, and very rarely occurs in children.(2,3) Familial occurrence has been described in the literature.(4,5) In our case patient is an middle aged female presenting for the first time.

JLIS is characterized by single or multiple erythematous papules or plaques and, less commonly, nodules, typically localized on the face, neck, chest, arms and upper back.(3) Our case also presented with similar features.

Sometimes an arciform configuration with central clearing is seen. Usually the lesions are asymptomatic, but they can be itching or burning. The relationship to sun exposure is variable and there is no regional variation in incidence.(3) In our case history of aggravation on exposure to sunlight is present.
CASE REPORT

Whether JLIS is a separate entity, or belongs to the disease spectrum of cutaneous lupus erythematosus or polymorphous light eruption is still a matter of debate, since clinical and histopathological features may overlap in particular with lupus erythematosus tumidus. Recent comprehensive studies conclude that these two conditions share more similarities than differences.(2,6) A few cases related to Borrelia burgdorferi infection or drugs have been reported.(7,8) Also, a few cases have been ascribed to contact allergy.(9)

Histopathologically JLIS is characterized by a superficial and deep, primarily perivascular, sleeve-like lymphocytic dermal infiltrate with a predominance of small mature polyclonal lymphocytes and without epidermal involvement.(2,10) Deposits of mucin in the reticular dermis have been described.(6) However, other authors have been unable to demonstrate mucin in JLIS.(2,11) In our case histopathology is in correlation with previous studies.

A variety of treatments has been tried, with variable, and often limited, success, including topical, intra-lesional or systemic corticosteroids, antimalarials, thalidomide, tetracyclines, cryotherapy and photo-protection. A few cases of successful treatment with dapsone, auranofin, and chemotherapy have been reported.(12–14)

In our case there was good response to hydroxy chloroquine 200mg bid, this is in concurrence with previous studies.(15)(16) Treatment with anti-malarials is usually effective in case with photosensitivity (Adamski et al. 2002).(17) In our case the evolution case is favourable with antimalarials.

Patient is under remission after 6 weeks. 1 year follow up was done, there were no recurrences. Prognosis is good, because lymphocytic infiltration of skin resolves spontaneously.
