HOW TO CITE THIS ARTICLE:

ABSTRACT: Meckel's diverticulum is a persistent remnant of the omphalomesenteric duct. It presents the most common congenital anomaly of the small intestine (1-4%). Common complications related to a Meckel's diverticulum include hemorrhage, intestinal obstruction, and inflammation. Small bowel obstruction due to mesodiverticular band of Meckel's diverticulum is a rare complication. Herein, we report the diagnosis and management of a small bowel obstruction occurring due to mesodiverticular band of a Meckel's diverticulum.

KEYWORDS: Mesodiverticular band; Meckels diverticulum, Intestinal obstruction.

INTRODUCTION: Meckel's diverticulum is the most common congenital anomaly of the gastrointestinal system.¹-² It originates from failure of the vitelline duct to obliterate completely, which is usually located on the antimesenteric border of the ileum. Its incidence is between 1% and 3%.³,⁴,⁵ Meckel's diverticulum occurs with equal frequency in both sexes, but symptoms from complications are more common in male patients. Most of the Meckel’s diverticula are discovered incidentally during a surgical procedure performed for other reasons. In symptomatic patients, a variety of presentation have been reported, including Hemorrhage, inflammation, intestinal obstruction, hernial involvement (littre hernia), umbilicus sinus or fistula and tumours⁶,⁷. Histologically, heterotopic gastric and pancreatic mucosa are frequently observed in the diverticula of symptomatic patients¹-². Involvement of the mesodiverticular band of the diverticulum is seen rarely.

CASE REPORT: A 24-year-old male got admitted to the emergency service of our hospital with severe abdominal pain and distension and vomiting one day prior to admission, with no history of previous abdominal surgery. On examining the abdomen there was distention and guarding present, and bowel sounds were absent. He was non-febrile. No masses were palpable. There was no significant medical history. Laboratory findings showed a leukocyte count of 8900/mm³, whereas the hemoglobin and platelet values were 11.4g/dl and 216, 000/mm³, respectively. All other studies, including electrolytes and urinalysis, were within normal limits. Erect abdominal film showed multiple air fluid levels on the film. On erect x-ray and USG it was diagnosed with mechanical intestinal obstruction, and nasal decompression and catheterization was done. Emergency exploratory laparotomy was performed under general anesthesia.

The distal part of the ileum was found to be markedly compressed by the mesodiverticular band within an area 70cm proximal to the end of the ileum (Figure 1). Ileal loops were dilated proximal to the obstruction. Obstruction was caused by trapping of a bowel loop by a mesodiverticular band. After separating the Mesodiverticular band, the ileal loop was released and
CASE REPORT

Meckel's diverticulum was found gangrenous and adherent to the proximal ileum (Figure 2). On separation of the adhesions perforated ileum was seen proximally from the diverticulum (Figure 3).

Resection of the Meckel's diverticulum and functional end-to-end anastomosis of the bowel were performed. The perforation was closed primarily (Figure 4). The patient recovered without any complications and was discharged after seven days of hospitalization and was followed up after three weeks and was doing fine.

The diverticulum was confirmed as Necrosed Meckel’s diverticulum by histological examination.

DISCUSSION: Meckel's diverticulum was originally described by Fabricius Hildanus in 1598. However, it is named after Johann Friedrich Meckel, who established its embryonic origin in 1809. Meckel's diverticulum is the most common congenital anomaly of the small intestine, with a prevalence of approximately 1–3%, and is a true diverticulum containing all layers of the bowel wall. The average length of a Meckel's diverticulum is 3cm, with 90% ranging between 1cm and 10cm. This diverticulum is usually found within 100cm of the ileocaecal valve on the antimesenteric border of the ileum. The mean distance from the ileocaecal valve seems to vary with age, and the average distance for children under 2 years of age is known to be 34cm. For adults, the average distance of the Meckel’s diverticulum from the ileocaecal valve is 67cm. Most cases that have Meckel's diverticulum are asymptomatic. Estimated risk for developing lifetime complications of the Meckel’s diverticulum is around 4%.

Most of the patients are asymptomatic, and the diagnosis is difficult to confirm preoperatively. Among the symptomatic patients, two types of heterotopic mucosa (gastric and pancreatic) are found histologically within the diverticula. The frequent complications of Meckel’s diverticulum are hemorrhage, intestinal obstruction, and diverticulitis. Intestinal obstruction is the second most common complication of Meckel's diverticulum.

The clinical manifestation of complicating Meckel's diverticulum are frequently non-specific and can mimic other pathological conditions such as appendicitis, crohn's disease, cholecystitis, and peptic ulcer.

Symptoms are most frequent during childhood and the frequency decreases with age. Elsayes et al. noted that bowel obstruction accounts for up to 40% of symptomatic Meckel's diverticula. There are lots of mechanisms for bowel obstruction arising from a Meckel's diverticulum. Obstruction can be caused by trapping of a bowel loop by a mesodiverticular band, a volvulus of the diverticulum around a mesodiverticular band, and intussusception, as well as by an extension into a hernia sac (Littre's hernia). Similarly, as in our case, obstruction can be caused by trapping of a bowel loop by a mesodiverticular band. The important aspect of our case is clear demonstration of the mesodiverticular band of a Meckel's diverticulum.

Unusual cases include mechanical obstruction related to peritoneal or mesodiverticular band, long Meckel's diverticulum encircling small bowel loops, gall stones at neck of diverticulum, axial torsion of diverticulum around its narrow base. Similarly, as in our case, obstruction can be caused by trapping of a bowel loop by a mesodiverticular band. The important aspect of our case is clear demonstration of the mesodiverticular band of a Meckel's diverticulum.

The preoperative diagnosis of Meckel’s diverticulum is often difficult, with only 6-12% of Being diagnosed correctly. Various imaging modalities have been used for diagnosing Meckel's diverticulum. Conventional radiographic examination is of limited value. Although of limited value, sonography has been used for the investigation of Meckel's diverticulum. High-resolution sonography...
usually shows a fluid-filled structure in the right lower quadrant having the appearance of a blind-ending, thick-walled loop of bowel. On computed tomography (CT), Meckel's diverticulum is difficult to distinguish from normal small bowel in uncomplicated cases. However, a blind-ending fluid or gas-filled structure in continuity with small bowel may be revealed. Abdominal CT is used for complicated cases such as intussusceptions. CT can help to confirm the presence of intussusception and distinguish between lead point and nonlead point intussusceptions.\textsuperscript{20, 21}

Among the asymptomatic patients, whether all incidental Meckel’s diverticula should be resected or not is an unresolved question. On the other hand, for the symptomatic patients, treatment should always include resection of the diverticulum or the segment of the bowel affected by the pathology.\textsuperscript{3, 8}

Surgical treatment of a Meckel's diverticulum generally consists of diverticulectomy, either by simple excision in the transverse axis of the ileum to avoid luminal stenosis, or by resection of the adjacent ileal wall or a segment of ileum with anastomosis. The latter is reserved for patients with complicated diverticula.\textsuperscript{8}

In conclusion, although Meckel's diverticulum is the most prevalent congenital abnormality of the gastrointestinal tract, it is often difficult to diagnose. Complicated Meckel’s diverticulum is very uncommon cause of small bowel obstruction.

The complications of Meckel’s diverticulum should be kept in mind in the differential diagnosis of small bowel obstruction.
